

This is how flooding can impact health

Flooding is devastating in every aspect: from property and infrastructure damage to loss of life and wider health impacts. As flooding becomes increasingly common for more people in a warming world, we look at its repercussions on human health.

Flooding is the most common natural disaster globally, <u>affecting more</u> <u>than two billion people worldwide between 1998 and 2017</u> and with <u>44%</u> <u>of disasters worldwide associated with it</u>.

As climate change makes the world increasingly susceptible to <u>extreme</u> <u>weather events</u>, more people are likely to experience flooding and its devastation, including its serious impacts on our health.

The Intergovernmental Panel on Climate Change (IPCC) Sixth Assessment Report published in March 2022 highlighted that <u>climate</u> <u>hazards such as flooding are "increasingly contributing to a growing</u> <u>number of adverse health outcomes"</u>.

Health impacts of flooding

The health impacts of disasters like flooding are complex and cascading, and can impact any one person or population simultaneously.

The kinds of health risks any given community might experience, the severity of them, and just how vulnerable they might be can differ <u>depending on various factors</u>. Geography, population size and density as well as levels of preparedness and resilience are part of it. The flood's characteristics also play into this, whether it's <u>flash floods</u>, coastal floods, riverine floods, or permanent floods for low-lying areas.

Floods can directly and indirectly affect <u>human health</u> in both the short and long term. Additionally, it's not just communities who have experienced flooding whose health is at risk. Disaster responders, healthcare professionals and critical service providers can also be affected.

Drowning is often top of mind when it comes to health risks of flooding. But the risks can range from injuries, hypothermia and animal bites to

infectious diseases, undernutrition and mental health problems.

When disasters like floods strike, there is a lot of focus on <u>economic</u> <u>impact</u> and property damage, as well as human casualties. But these also overlap with health concerns in many ways.

Flooding can strain health services due to damaged infrastructure, loss of health professionals and access to medicine, which could delay care or treatment for those who need it.

The economic fallout or loss of possessions and livelihoods due to a flooding disaster can result in financial uncertainty that may affect mental health, to say nothing of the grief from losing loved ones.

Below is an overview of common flooding related health impacts.

Diseases

Diseases and outbreaks are <u>another major health concern in the event of</u> <u>flooding</u>.

These can come in the form of <u>waterborne diseases</u>, which are those that <u>come from drinking or coming into contact with contaminated water</u>. These can include diarrhea, cholera, typhoid fever and leptospirosis.

It can also sometimes be <u>vector-borne diseases</u>, which <u>come from an</u> <u>intermediate species carrying the disease pathogen like a mosquito</u>. Vector-borne diseases that come about from flooding include <u>dengue</u> <u>fever</u> and malaria.

Flooding increases the risk of these diseases and potential outbreaks in populations because it can cause sewage overflow as well as damage to water supply and sanitation facilities. Contamination of drinking water

can lead to typhoid fever, cholera and hepatitis A.

In areas at risk of coastal flooding, there's also the possibility of <u>salt-</u> water intrusion to drinking water as well as hypertension and eclampsia.

Once floodwaters have receded, stagnant water left behind in gardens, parts of the home or even farming lands can become a breeding ground for mosquitoes and lead to diseases like dengue or malaria.

Bangladesh had its worst dengue outbreak in 2019, with <u>over 100,000</u> <u>cases and 179 deaths</u>. The outbreak was <u>attributed to flooding in that</u> <u>year's monsoon season</u>.

Additionally, displacement and eventual overcrowding in evacuation centers can bring about other issues such as <u>pulmonary and systemic</u> <u>fungal infections</u> from molds. According to the European Climate and Health Observatory, people that have evacuated to temporary shelters are more likely to be exposed to <u>infectious diseases</u> and pathogens, so are <u>"more prone" to health problems</u>.

Injuries can also potentially lead to infections or diseases such as leptospirosis, a disease that spreads through water contaminated with rodent urine <u>coming into contact with the skin</u>.

In the Philippines—the third most vulnerable country to natural hazards and among the most at risk from climate change—there have been increases in <u>leptospirosis, typhoid fever</u> and <u>dengue</u> after heavy rainfall and flooding.

Mental health problems

Mental health problems, which can occur later, are often overlooked and not as well studied relative to the immediate health impacts caused by

flooding. So far, it is known that the experience of surviving a flooding disaster can impact people after the event and sometimes for many years down the line.

Anxiety, depression, <u>post-traumatic stress disorder</u> or PTSD, psychosis and insomnia are some of the common mental health problems that come up in the aftermath of a flooding disaster.

In the U.K., flood victims were <u>between 4 to 8.7 times at risk</u> of longterm mental health problems compared to people who did not experience flooding. In one case, <u>rain became a trigger for a woman's PTSD after</u> <u>experiencing flooding in 2000</u>.

The process of <u>clean-up</u>, <u>recovery and rebuilding can be a source of</u> <u>stress</u>, more so if they are not managed well by both government and the private sector.

Disruptions to basic facilities and supplies such as electricity, water and food can likewise be distressing and impact mental health, especially when these are prolonged.

In July 2021, <u>heavy rainfall contributed</u> to some of the <u>worst flooding</u> <u>Western Europe has seen in decades</u>, with over 200 casualties and billions of euros worth of damage. The <u>World Health Organization</u> <u>issued public health advice</u> on the long-term health impacts stemming from disrupted access to essential services and slow recovery. The Center for Disaster Philanthropy then <u>highlighted mental health as a top</u> <u>priority</u> for those affected.

Undernutrition or malnutrition

Though rarely considered, despite evidence for it, <u>undernutrition or</u> <u>malnutrition is another health impact</u> that can result from flooding

disasters. Victims have been known to eat less during or after flooding, and often lose access to regular food supplies.

Food systems such as agriculture can also be significantly disrupted because of flooding. This can affect both the quantity and quality of food available and <u>lead to food insecurity and undernutrition</u>.

In parts of South Sudan, flooding in the last three years led to the displacement of hundreds of thousands of people with <u>many resorting to</u> <u>eating wild food such as water lilies</u> owing to the loss of crops and livestock as food sources. Around 2.5 million people were estimated to <u>be at risk of severe food insecurity</u>.

Adapting to the future

Climate change is already exacerbating flooding as warmer temperatures can increase precipitation and cause extreme weather events.

Around <u>86 million more people have become exposed to flooding from</u> <u>2000 to 2015</u>.

What can we do?

Learning to adapt will be crucial to deal with the health impacts of flooding, alongside mitigation efforts such as reducing emissions.

In Europe alone it's estimated that without preventive measures <u>up to 2.2</u> <u>million people will be exposed to coastal flooding by 2100</u>. That number goes down to 1.4 million people with moderate mitigation measures but without adaptation, and as low as 0.6 million if adaptation is factored in.

The health impacts of flooding can only get worse if the world does not take decisive and swift action on <u>climate change</u>.
