Patients recently diagnosed with type 1 diabetes have greater death of pancreatic β -cells compared with patients with long-standing diabetes, which can be reduced by treatment with teplizumab, according to a study published online Feb. 19 in *Diabetes*.

(HealthDay)—Patients recently diagnosed with type 1 diabetes have greater death of pancreatic β -cells compared with patients with long-standing diabetes, which can be reduced by treatment with teplizumab, according to a study published online Feb. 19 in *Diabetes*.

Jasmin Lebastchi, from the Yale University School of Medicine in New Haven, Conn., and colleagues compared β -cell death in 43 patients recently diagnosed with type 1 diabetes, 31 individuals without diabetes, and 37 patients with type 1 diabetes treated with teplizumab or placebo. β -cell death was determined by measuring relative levels of unmethylated *INS* DNA in serum.

The researchers found that, compared with individuals without diabetes, patients with recent-onset diabetes had higher rates of β -cell death, while patients with long-standing diabetes had lower levels of β -cell death. After treatment of recent-onset diabetes patients with teplizumab, β -cell death was significantly reduced and β -cell function was significantly better preserved.

"Improvement in C-peptide responses with immune

intervention is associated with decreased β -cell death," Lebastchi and colleagues write.

Several authors have [patent applications](#) for teplizumab and/or the assay of unmethylated insulin DNA and are on the scientific advisory board of Islet Sciences.
