

Lithium may protect against cartilage decline in osteoarthritis

27 June 2014

"LiCl reduced catabolic events in IL-1 β -treated human articular chondrocytes and attenuated the severity of cartilage destruction in IL-1 β -treated mouse femoral head explants and in the knee joints of mice with surgically induced OA," the authors write.

(HealthDay)—Lithium reduces catabolic events in interleukin-1 β (IL-1 β)-treated human articular chondrocytes and protects against cartilage degradation in IL-1 β -treated mouse knee joints, according to a study published in the May issue of *Arthritis & Rheumatology*.

Takeshi Minashima, Ph.D., from New York University, and colleagues treated human articular chondrocytes with lithium chloride (LiCl) and IL-1 β . Real-time polymerase chain reaction then determined expression levels of catabolic genes. Additionally, the activation of NF- κ B was determined using luciferase reporter assays. Immunoblot analysis of total cell lysates determined the activities of MAPKs and the STAT-2 signaling pathway.

The researchers found that LiCl treatment resulted in decreased catabolic marker messenger RNA levels and activation of NF- κ B, p38 MAPK, and STAT-3 signaling in IL-1 β -treated articular chondrocytes. LiCl also directly inhibited IL-6-stimulated activation of STAT-3 signaling. Eight weeks after osteoarthritis induction surgery, the severity of cartilage destruction in LiCl-treated mouse knee joints or in LiCl-treated mouse femoral head explants after IL-1 β treatment were markedly reduced versus in vehicle-treated joints or explants.
