

New study of self-awareness in MS has implications for rehabilitation

22 August 2014

A new study of self-awareness by Kessler Foundation researchers shows that persons with multiple sclerosis (MS) may be able to improve their self-awareness through task-oriented cognitive rehabilitation. The study was published ahead of print on July 2 in *NeuroRehabilitation*. Self-awareness is one's ability to recognize cognitive problems caused by brain injury. This is the first study of self-awareness in MS that includes assessment of online awareness, as well as metacognitive awareness.

Yael Goverover, PhD, OT, is a visiting scientist at Kessler Foundation. She is an associate professor at New York University. Dr. Goverover is a recipient of the National Institute on Disability and Rehabilitation Research Fellowship award (Mary Switzer Award). Drs. Genova, Chiaravalloti and DeLuca are MS researchers at Kessler Foundation.

The researchers assessed 18 people with MS and 16 healthy controls for 2 types of [self-awareness](#) - metacognitive knowledge of disabilities (or intellectual [awareness](#)) and online awareness (emergent or anticipatory awareness). They also looked at the relationships among self-awareness, functional performance and quality of life (QoL). Assessment involved the Functional Behavior Profile, questionnaires administered before and after functional tasks (purchasing cookies and airline tickets via the Internet) and the Functional Assessment of Multiple Sclerosis measure.

"Results showed that compared with controls, people with MS assessed their actual performance more realistically following completion of a task. This suggests that individuals may be able to improve their self-awareness through more experience with tasks," noted Nancy Chiaravalloti, PhD, director of Neuropsychology & Neuroscience Research at Kessler Foundation. "Research that leads to better understanding of types of self-awareness, functional outcomes and QOL will aid

the development of effective assessments and rehabilitation interventions," said Dr. Chiaravalloti. "The association between online awareness and task performance in this study, for example, may have implications for [cognitive rehabilitation](#) strategies in the MS population."
