(HealthDay)—For ureteral stones, extracorporeal shock wave lithotripsy delivered at a shock wave delivery rate of 90 pulses per minute is associated with excellent outcomes, according to a study published in the August issue of *The Journal of Urology*.

Daniel P. Nguyen, M.D., from the University of Bern in Switzerland, and colleagues compared the outcomes of two delivery rates in a [prospective randomized trial](#) involving 254 consecutive patients with solitary ureteral stones. Participants were randomized to receive extracorporeal shock wave lithotripsy at a shock wave delivery rate of 60 and 90 pulses per minute (130 and 124 participants, respectively).

The researchers found that at three months, the stone-free rate was significantly higher in patients who underwent extracorporeal shock wave lithotripsy at a shock wave delivery rate of 90 pulses versus 60 pulses per minute (91 versus 80 percent; $P = 0.01$). The observed difference was due to patients with proximal (100 versus 83 percent; $P = 0.005$) and mid ureteral (96 versus 73 percent, respectively; $P = 0.03$) stones, but not those with distal ureteral stones (81 versus 80 percent; $P = 0.9$). Independent predictors of success included shock wave delivery rate of 90 pulses per minute, proximal stone location, stone density, stone size, and an absent indwelling
