

Moderate, more severe hearing impairment linked to mortality

September 26 2015

(HealthDay)—For older adults with hearing impairment (HI), moderate or more severe impairment is associated with mortality in an age-adjusted model, according to a research letter published online Sept. 24 in *JAMA Otolaryngology-Head & Neck Surgery*.

Kevin J. Contrera, M.P.H., from the Johns Hopkins University School of Medicine in Baltimore, and colleagues used combined data from National Health and Nutrition Examination Surveys to examine 1,666 adults aged 70 years and older who had undergone audiometric testing (527 without HI; 1,139 with HI). The authors examined the correlation between HI and [mortality](#).

The researchers found that, compared to individuals without HI,

mortality was significantly increased for those with moderate or more severe HI (hazard ratio [HR], 1.54; 95 percent confidence interval [CI], 1.08 to 2.18) and increased for those with mild HI (HR, 1.27; 95 percent CI, 0.83 to 1.95), in an age-adjusted model. The risk was attenuated after further adjustment for demographic characteristics and cardiovascular risk factors (moderate or more severe HI: HR, 1.39; 95 percent CI, 0.97 to 2.01; mild HI: HR, 1.21; 95 percent CI, 0.81 to 1.81).

"Future studies are required to explore the basis of the association of HI with mortality and to determine whether therapies to rehabilitate hearing can reduce mortality," the authors write.

One author disclosed financial ties to Cochlear, Autifony, Pfizer, Med-El, and Amplifon.
