fathers' involvement in raising children in other areas of [children's](#) development, and our study suggests that there may be benefits to child health as well," said Dr. Michelle Wong, lead author of the *Obesity* study. "While due to data limitations we could only consider the involvement of fathers, it is also important to understand the relative caregiving involvement of both mothers and fathers."

Fathers are becoming more involved with raising children, but limited research has examined their association with childhood obesity. In a recent study, fathers' increased involvement with child caregiving was linked with a decreased likelihood that their children would become obese from age 2 to 4.

In the study, which used data from a survey conducted in a nationally representative sample of children in the United States, increases in [fathers'](#) participation in physical child care (such as bathing and dressing children) and the frequency that they took children outside for walks and playtime were linked with a decreased likelihood of obesity in their young children.

The findings suggest that encouraging fathers to increase their involvement with raising children and including fathers in [childhood obesity](#) prevention efforts may help reduce obesity risk among [young children](#).

"There is growing evidence of the importance of
