

68Ga-somatostatin analog PET-CT linked to reduced costs

20 July 2017

SCGH and RPH, respectively, for ^{111}In -octreotide scintigraphy. For ^{68}Ga -somatostatin analog PET-CT, the effective dose was 8.7 to 10.7 mSv. The average cost was four times lower for ^{68}Ga -somatostatin PET-CT versus ^{111}In -octreotide scintigraphy.

" ^{68}Ga -somatostatin analogue PET-CT is not only more accurate than ^{111}In -octreotide [scintigraphy](#), this study has also shown that it is significantly less expensive, delivers a lower [radiation](#) dose to patients, and requires less imaging time for patients and staff," the authors write.

(HealthDay)—For imaging neuroendocrine tumors, ^{68}Ga -somatostatin analog positron emission tomography-computed tomography (PET-CT) is associated with reduced costs compared with ^{111}In -octreotide scintigraphy, according to a study published online July 17 in the *Journal of Medical Imaging and Radiation Oncology*.

Tatiana Segard, M.D., from Sir Charles Gairdner Hospital (SCGH) in Nedlands, Australia, and colleagues conducted an analysis based on retrospective clinical data from 95 ^{111}In -octreotide scintigraphies performed in 2007 and 2008 in SCGH and Royal Perth (RPH) hospital and 219 ^{68}Ga -somatostatin analog PET-CT studies conducted at SCGH in 2013. The authors derived whole body effective radiation dose from the radiopharmaceutical and low-dose CT scan. Radiopharmaceutical and imaging [costs](#) were included in the cost analysis.

The researchers found that the mean effective radiation dose was 18.1 mSv and 13.8 mSv at
