

Link confirmed between obesity and better outcomes following heart procedures

2 August 2017

Research undertaken at University Hospitals of North Midlands NHS Trust (UHNM) has confirmed a link between elevated body mass index (BMI) and patients having better survival outcomes following percutaneous coronary interventions (PCI).

PCI is a non-surgical procedure used to treat narrowing of the coronary arteries, improving blood flow to the heart. This study, funded by UHNM Charity, looked at data from all PCI procedures undertaken in the UK between 2005 and 2013.

This research found that the BMI of patients undergoing PCI procedures has increased over time. It was also found that those patients with a higher BMI, specifically overweight patients, have far fewer complications and better clinical outcomes compared to either [normal weight](#) or underweight patients.

The link between higher BMI and better clinical outcomes supports the obesity paradox. This is a medical theory whereby [overweight patients](#) tend to have better outcomes for a number of different cardiovascular conditions than either patients of a 'normal' weight or underweight patients.

Prof Mamas Mamas, Consultant Cardiologist at UHNM and Professor of Cardiology at Keele University, led this research, alongside Dr Eric Holroyd, Consultant Cardiologist at UHNM, and other colleagues from the Trust.

Prof Mamas said: "We have found that patients over time are becoming heavier and more obese. For many years fat tissue was considered an inert tissue, but we now know that it releases hormones and other substances that may have a protective effect on patients.

"The important thing to say is that patients shouldn't try to become obese in the hope that it will improve their outcomes. The effect size of this

study was small, and obesity is associated with significant problem such as cancer, diabetes development and cardiovascular risk, so patients should maintain a healthy weight.

"More work will be required to understand the obesity paradox, whether it is a real biological phenomenon or whether it is driven by unmeasured facts such as obese patients being younger and therefore healthier overall, compared to more elderly and frail [patients](#) that are underweight or of normal [weight](#)."
