

# Doctors are prescribing opioids for shorter duration, lower doses in children

January 29 2019

---

As the opioid epidemic continues to plague the United States, physician-researchers at Children's Hospital of Philadelphia (CHOP) analyzed prescription patterns in children. They found that both duration of treatment and dose amounts declined between 2013 and 2017, while the rate of prescribing remained the same.

The findings were published January 17, 2019 in *Pain Medicine*.

Researchers analyzed 65,190 pediatric cases between 2013 and 2017 across nine different surgical specialties in the CHOP Network. They found that while rates of prescribing remained stable, doctors prescribed opioids for shorter durations and lower individual dose amounts. While that trend is encouraging, researchers also found that doctors were more likely to prescribe opioids to females, ethnic minorities and patients with public insurance.

"The trends we saw in our study are reassuring," says Ronald S. Litman, DO, corresponding author and an anesthesiologist in the Department of Anesthesiology and Critical Care Medicine at CHOP. "However, we are concerned about the bias we found in prescribing trends, and need to better understand why doctors are prescribing certain patients more opioids."

The rate of fatal overdoses from legally prescribed opioids, such as oxycodone or hydrocodone, has risen steadily from 2000 to 2015, eventually matching rates of fatal heroin overdoses. Studies show that

living in a home with a prescription [opioid](#) user is linked to an increase risk in abusing the medication and may lead to [opioid addiction](#). In recent years, the Centers for Disease Control and Prevention have published revised pain treatment guidelines that emphasize a shorter duration of opioid prescription to combat the [opioid epidemic](#) in the United States.
