

Quinn on Nutrition: Carbs—how low can we go?

"Fruit has carbs? I had no idea," a stunned patient told me recently.

She's not the only one who doesn't have a complete understanding of carbohydrates—the focus of our current craze for low carb foods.

I find that many people who say they "don't eat carbs" may not really understand what a carb is...and isn't.

Simply put, carbohydrates are sugars and starches that occur naturally in plants. Carbs are also a natural ingredient in milk as lactose, or milk sugar—the first sweet that babies taste.

Plants convert energy from the sun into sugars (such as fructose in fruit) and starches in grains and beans. Thus, most of the calories in plant foods come from carbohydrates. And we get plenty of added carbs in sweets and treats made with honey, syrups and refined beet and cane sugars.

Carbohydrates are not the boogey man. In fact, they are the most efficient source of energy for

muscle, brain and nerve cells. That's why current dietary guidelines recommend 45% to 65% of our daily calories come from carbs. Athletes, who need higher amounts of readily available fuel for their hard working muscles, generally ingest carbs at the higher end of this scale. People with diabetes, who need to avoid excessive amounts of carbs, are often at the lower end.

There is a difference, however, between a [low carb diet](#) and a VERY low carb [diet](#). Many of the popular low carb plans allow just 10 to 20% of daily calories from foods such as fruit, grains, vegetables and milk. By default, that means the highest proportion of calories with these diets come from protein, fat or alcohol.

When the body is deprived of adequate carbohydrates for energy, it turns to other sources. Muscles, for example, can use fat; the brain cannot. But it can use the breakdown products of fats called ketones. This is the basis premise for ketogenic or very low carbohydrate diets.

Our view on extremely low carbohydrate diets is still evolving. Although they are often deficient in major nutrients such as [dietary fiber](#), calcium and vitamin C, many people love these diets. By virtue of their high protein and fat content, they keep hunger at bay which helps with weight loss. Many studies also report that low carb diets can effectively lower blood sugars and improve other health parameters.

Perhaps the hardest thing about extremely low carb diets is sticking with them long term. Birthday cake and 4th of July watermelon are hard to avoid forever.

Nutrition-wise, somewhere between the two extremes of very low to very high carbohydrate diets, is where most of us would probably do best. Moderate amounts of carbs with our meals assures a better balance of nutrients and an adequate

supply of dietary fiber—a non-digestible [carbohydrate](#) used by the body to feed the healthful bacteria in our guts.

Studies have found that as few as 70 and up to as many as 265 grams of [carbs](#) a day can accomplish similar health goals—if we pay attention to the quality of the foods we choose.
