

# Toxin promotes cattle-to-cattle transmission of deadly *Escherichia coli* strains

October 3 2019

Stx2 mediated inhibition of bovine intestinal epithelial proliferation. Normal intestinal epithelial proliferation and differentiation (left) is driven by active stem cells located at the base of crypts. Stem cells continuously generate proliferating progeny that differentiate into the various cell lineages of mature intestinal villi and migrate up the crypt toward the villus tip. Continuous generation of new intestinal epithelial cells is balanced by apoptosis of older cells at the luminal surface resulting in the rapid turnover of intestinal epithelial cells.

Expression and release of Stx2 into the intestinal crypt (right) by colonising Stx2+ EHEC O157 is proposed to inhibit normal stem cell driven proliferation. Inhibition may be direct by Stx2 binding to and inactivating Gb3+ stem cells or indirect inhibition of stem cells by interaction of Stx2 with as yet unidentified Gb3+ cells in the base of the crypt. *E. coli* O157 colonises at the luminal surface and further inhibits local epithelial turnover by type 3 secretion system-mediated delivery of specific effectors that can inhibit apoptosis. Shiga toxin subtype 2a (Stx2a) may play a key role in promoting the colonization and transmission of life-threatening *Escherichia coli* strains in cattle, according to a study published October 3 in the open-access journal *PLOS Pathogens* by Tom McNeilly of the Moredun Research Institute, David Gally of the University of Edinburgh, and colleagues. As these bacteria evolve ways to increase the activity of Shiga toxins, they may become more of a threat to human health.

Specific *E. coli* strains infected with viruses that produce Shiga [toxin](#) can be a threat to [human health](#), leading to [severe symptoms](#) including bloody diarrhea and kidney damage. In many countries, the most serious symptoms in humans are associated with *E. coli* strains that express Stx2a. For example, *E. coli* O157 strains that express the Stx2a subtype are associated with life-threatening human infections in the UK. By contrast, these strains do not produce symptoms in cattle—a natural reservoir host. The role of this toxin in the animal reservoir is still not entirely clear.

In the new study, McNeilly and Gally tested whether Stx2a is important for calf-to-calf transmission by comparing *E. coli* O157 strains with and without Stx2a. They found that Stx2a is produced rapidly, restricts the growth of bovine gastrointestinal organoids, and plays a role in establishing *E. coli* O157 colonization in the bovine gastrointestinal tract.

The findings also show that Stx2a facilitates effective cattle-to-cattle transmission and may have led to the expansion of Stx2a producing *E. coli* O157 strains in cattle populations. The authors propose a model in which Stx2a enhances *E. coli* O157 colonization by restricting the regeneration and turnover of the tissue lining the gut. According to the authors, research in this area highlights the value of understanding Shiga toxin activity and drivers for its selection and maintenance in the animal reservoir, which may inform strategies that can reduce the threat to human health.

"This study demonstrates for the first time an important role for Shiga toxin subtype-2a (Stx2a) in enhancing transmission of Escherichia coli O157 between cattle, the most important reservoir of infection for these dangerous human pathogens," adds McNeilly. "This explains the successful emergence of Stx2a positive *E. coli* strains in cattle populations, and has consequences for human infections as strains encoding Stx2a are more likely to cause severe human disease."

Gally comments, "The study is important as it explains why the Stx2a toxin subtype has become common in *E. coli* O157 [strains](#) in [cattle](#): (1) that it can be produced more rapidly compared to some other Stx subtypes and so has taken over; (2) that it provides an advantage in the animal host by halting the usual turnover of gut cells that would remove adherent *E. coli*, so the bacteria colonise more easily, persist in the gut and can be excreted at high levels to go onto infect other animals and humans."
