

Test vaccine elicits strong response to SARS-CoV-2 in mice

6 April 2020

MERS-CoV [vaccine](#) was comprehensively tested when delivered subcutaneously by traditional needle injection or intracutaneously by dissolving MNAs.

The researchers found that MERS-S1 subunit vaccines delivered by MNA elicited strong and long-lasting antigen-specific antibody responses. Clinically translatable MNA SARS-CoV-2 subunit vaccines were designed and produced within four weeks of identification of the SARS-CoV-2 S1 sequence. These MNA-delivered SARS-CoV-2 S1 subunit vaccines elicited potent antigen-specific antibody responses, which were seen starting two weeks after immunization.

"Testing in patients would typically require at least a year and probably longer," a coauthor said in a statement. "Recently announced revisions to the normal processes suggest we may be able to advance this faster."

Microneedle array (MNA) delivery of trimeric coronavirus spike (S) protein subunit vaccines seems promising for immunization against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection, according to research published online April 2 in *EBioMedicine*.

Noting that coronavirus S protein is considered a key target for vaccines for prevention of coronavirus infection, Eun Kim, from the University of Pittsburgh School of Medicine, and colleagues report on the development of MNA-delivered Middle East Respiratory Syndrome (MERS) Coronavirus (MERS-CoV) vaccines and their preclinical immunogenicity. Codon-optimized MERS-S1 subunit vaccines fused with a foldon trimerization domain were generated to mimic the native viral structure. Immune stimulants were engineered into this trimeric design in variant constructs. By evaluating virus-specific immunoglobulin G antibodies in the serum of vaccinated mice and using virus neutralization assays, the preclinical immunogenicity of the
