

Once a coronavirus vaccine exists, this researcher's mailable patch could deliver it to millions

14 May 2020, by Greg Weatherford

Guizhi "Julian" Zhu, Ph.D., an assistant professor in the School of Pharmacy's Department of Pharmaceutics, has been working on a patch that could be used for vaccines, including a vaccine for the coronavirus once it is developed. Credit: Danny Tiet, VCU School of Pharmacy

Someday, hundreds of millions of vaccinations against the coronavirus that causes COVID-19 could show up in people's mailboxes and be applied as simply as slapping on a Band-Aid.

That's the vision of Guizhi "Julian" Zhu, Ph.D., at the Virginia Commonwealth University School of Pharmacy.

Zhu, an assistant professor in the school's Department of Pharmaceutics, is researching a way to use tiny needles embedded in a small [patch](#) to give vaccinations.

"People, no matter who they are, can apply the patch to their own arm," Zhu said. "And that's it. People are vaccinated."

Laboratories and governments around the world are racing to find and test a [vaccine](#) to protect against the deadly [coronavirus](#)—a process that most experts say will take at least a year.

But even when a vaccine is ready, another enormous hurdle will remain: delivering that vaccine to millions or even billions of people.

If successful, his design for a vaccine patch offers a number of advantages over standard vaccinations, Zhu said.

For example, it would be relatively simple to send vaccines directly to people by using the mail system—each vaccine patch is about the size of a little fingernail and would fit easily inside an envelope.

Another plus: Since the patches would be easy to apply, the method would reduce the need for people to travel to health care centers, many of which have been overburdened during the pandemic. This would minimize risk to the people most at risk for the disease, who are older and sicker than the general population, as well as to vital health care workers.

Zhu's design looks similar to nicotine patches used in smoking-cessation products. But it works very differently.

Nicotine patches allow chemicals to seep through the skin. But that is not a practical approach for vaccines. Instead, Zhu's design uses more than a hundred polymer microneedles—each as thin as a human hair—on each patch to get through the skin.

"It's not painful, not like a syringe," Zhu added.

These microneedles would dispense harmless

synthetic fragments of the virus embedded in a protective ball of nanoparticles that dissolves once it enters the body. The fragments, while doing no harm themselves, would teach the body's defense system to recognize and attack any real COVID-19 viruses that appear.

Zhu's research, funded in part by the Department of Pharmaceutics and VCU's Center for Pharmaceutical Engineering and Sciences, was one of the first 20 proposals to receive grants from the VCU COVID-19 Rapid Research Funding Opportunity.

"This is the kind of impactful research the program is designed to support and the kind of inventive thinking that will help us successfully fight the novel coronavirus," said P. Srirama Rao, Ph.D., VCU's vice president for research and innovation. "The microneedle patch could potentially change the delivery of other vaccines now typically administered in a medical setting."

Zhu also has experience in developing targeted drug delivery systems and cancer nanomedicines. He is an associate member of the Developmental Therapeutics research program at VCU Massey Cancer Center.

With support from the VCU School of Medicine lab of Aron Lichtman, Ph.D., Zhu is working on preclinical studies to be sure the patches will deliver predictable doses of vaccines embedded in the protective nanoparticles.

He also will be testing to ensure the patches remain effective over extended times and in the varying temperatures they would encounter in mailboxes.

"It's our best hope that we can test to confirm this [design] within the next six months," Zhu said.

If the tests are successful, he added, the next step would be to make plans to manufacture the patches when a vaccine is ready and prepare for clinical testing.
