

# With or without allergies, outcomes similar for hospitalized patients with COVID-19

13 November 2020

During the COVID-19 pandemic, attention has been focused on how those with both allergies and asthma might be affected should they become ill. A new study being presented at this year's virtual American College of Allergy, Asthma and Immunology (ACAAI) Annual Scientific Meeting examines hospital data to determine if those with allergic conditions had more severe COVID-related disease than those without.

"We examined the charts of 275 patients admitted to the hospital who tested positive for the SARS-CoV-2 virus for any history of allergic disease," said allergist Dylan Timberlake, MD, ACAAI member and lead author of the study. "Over the two-month period when we examined the charts, we found the severity of disease didn't seem to differ between COVID-19 patients with allergies, versus COVID-19 patients without allergies."

Factors considered to determine severity of disease included ICU admission, length of stay, supplemental oxygen requirement and intubation rate.

"In looking at the outcomes for patients based on allergic diseases such as [allergic rhinitis](#), asthma, eczema, and food allergy, we didn't find significant differences in the numbers of interventions needed for those with allergies versus those without when it came to COVID-19," says allergist Mitchell Grayson, MD, ACAAI member and co-author of the study. "For example, with regard to ICU admission, 43% of those with allergic disease were admitted versus 45% without. And 79% of those with [allergy](#) needed [supplemental oxygen](#) versus 74% of those without."

In the study, more patients with allergies had COPD (39% vs. 17%), which is a known risk factor for severe disease with COVID. After statistically controlling for the presence of COPD and its association with more severe COVID-related illness, the researchers found a statistical trend

suggesting possible protection in those with pre-existing allergic [disease](#) but not asthma.
