

# Fight or flight response may hinge on protein in skeletal muscular system

Researchers at the University of Cincinnati say a regulatory protein found in skeletal muscle fiber may play an important role in the body's fight or flight response when encountering stressful situations.

The protein, fast skeletal [myosin](#) binding protein-C (fMyBP-C), plays a foundational role in the proper regulation of contractile structure and function in the body's fast twitch muscles—these muscles produce sudden bursts of power to sprint into action, jump or lift heavy objects. Fast skeletal myosin binding protein-C modulates the speed and force of fast skeletal [muscle](#) contraction.

"This response is very critical for the higher animal and human survival. Just imagine, you are walking through a forest and suddenly you see a tiger in front of you," says Sakthivel Sadayappan, Ph.D., a professor in the UC Division of Cardiovascular Health and Disease. "You will immediately act, either to fight or run away from the animal. For that action, fast muscle is essential, and fast myosin binding protein-C is the key molecule to regulate the speed of action."

Myosin-binding protein-C is a thick filament [regulatory protein](#) found in striated muscle in both the heart and skeletal system. The protein performs different functions in the two organs,

regulating contractility in the heart and playing a role in the development of fast and slow muscle fibers in skeletal muscle tissue.

Sadayappan along with researchers at UC College of Medicine, Florida State University, the University of Massachusetts Medical School and the Illinois Institute of Technology published research in the scholarly journal *PNAS* to further the understanding of the protein in skeletal function and regulation.

The study's lead author is Taejeong Song, Ph.D., a postdoctoral fellow in the Sadayappan Lab at the UC College of Medicine.

Song says that research examined the role of the protein in fast-twitch muscles by generating a [knockout mouse](#)—an animal in which researchers have either inactivated, replaced or disrupted the existing fast myosin binding protein-C gene to study its impact.

"We found that knockout mice demonstrated a reduced ability to exercise, showed less maximal

muscle force and a diminished ability for muscle to recover from injury," explains Sadayappan. "Our study concludes that fast myosin binding protein-C is essential in regulating the force generation and speed of contraction of fast muscles."

Song says advancing the knowledge of fast myosin binding protein-C may someday assist in addressing skeletal muscular disorders.

"Individuals lose their ability of muscle force generation for various reasons," says Song. "They may be extremely inactive or hospitalized for long periods of time. Aging may also be the cause for some. We also think if we can manipulate the workings of fast myosin binding protein-C in skeletal muscle that we can prevent or at least slow down the loss of muscle function in genetic muscle disease such as distal arthrogryposis. Our research is trying to figure out this problem in human health."

Other co-authors in the study from UC include Lisa Martin, senior research assistant in the Division of Cardiovascular Health and Disease; Judith Heiny, Ph.D., professor of pharmacology and systems physiology; and John Lorenz, Ph.D., professor of pharmacology and systems physiology.
