

New research on why mutations in a gene leads to mitochondrial disease

27 April 2021

Monash University researchers have uncovered for the first time the reason mutations in a particular gene lead to mitochondrial disease.

The finding, published in *PNAS* journal and led by Professor Mike Ryan from Monash University's Biomedicine Discovery Institute, shows that a gene responsible for causing loss of vision and hearing, TMEM126A, makes a protein that helps build an important [energy](#) generator in mitochondria. So, if this gene is defective, it reduces [mitochondrial function](#) and impares [energy production](#), uncovering why mutations lead to the [disease](#).

Mitochondria are [critical structures](#) within living cells that play a central role in energy conversion and their job is to process oxygen and take in the sugars and proteins from the food we eat to

produce the energy our bodies need to function properly. Mitochondria produce 90 percent of the energy our body needs to function.

Mitochondrial disease is an inherited, [chronic illness](#) that can present at birth or develop later in life and occurs when mitochondria fail to produce enough energy for the body to function properly. The cells of the optic nerve and the inner ear are particularly sensitive to mitochondrial defects due to the high energy requirements to transfer information to the brain, but Mitochondrial diseases can affect almost any part of the body.

Using a combination of cutting-edge technologies, the study found that loss of TMEM126A results in an isolated complex I deficiency—a common form of [mitochondrial disease](#) where a critical enzyme called complex I is reduced—and that the TMEM126A protein binds to a number of complex I subunits and additional proteins that help build the enzyme, known as assembly factors.

"Now we know that TMEM126A is important in helping to build this protein needed to provide energy for the mitochondria organelles, we can look at future therapies that can perhaps bypass TMEM126A function and find other ways to help cells make energy," Professor Ryan said.

First author Dr. Luke Formosa adds: "Now that we know what TMEM126A does in mitochondria, we can start to investigate treatments that might work for individuals with mutations in this gene, which could lead to less severe loss of vision and hearing."
