

Malaria booster vaccine continues to meet WHO-specified 75% efficacy goal

September 11 2022

Researchers from the University of Oxford and their partners have today reported new findings from their Phase 2b trial following the administration of a booster dose of the candidate malaria vaccine, R21/Matrix-M—which previously demonstrated high-level efficacy of 77% over the following 12 months in young west African children in 2021.

In their findings (reported in *The Lancet Infectious Diseases*), they found that a [vaccine booster](#) dose at one year following a primary three-dose regime maintained high efficacy against malaria, and continued to meet the World Health Organization's Malaria Vaccine Technology Roadmap goal of a vaccine with at least 75% efficacy.

The authors report from a Phase IIb randomized, controlled, [double-blind trial](#) conducted at the Clinical Research Unit of Nanoro (CRUN) / Institut de Recherche en Sciences de la Santé (IRSS), Burkina Faso. A total of 450 participants aged five to 17 months were recruited from the catchment area of Nanoro, with 409 receiving the booster.

The participants were randomly assigned to three groups, with the first two groups receiving the R21/Matrix-M (with either a low dose or high dose of the Matrix-M adjuvant) vaccine as a booster and the third a [rabies vaccine](#) as the [control group](#). Each child received the same booster vaccination as their primary series of vaccinations. Doses were administered in June 2020, largely prior to the peak malaria season.

The researchers report a vaccine efficacy of 80% in the higher-dose adjuvant group, and 70% in the lower dose adjuvant group, over 12 months of follow-up. Antibody levels were restored to similar levels as those following the primary vaccinations 28 days after the booster doses were administered. No serious adverse events related to the vaccine were noted.

Halidou Tinto, Professor in Parasitology, Regional Director of IRSS in Nanoro, and the trial Principal Investigator, said, "It is fantastic to see such high efficacy again after a single booster dose of vaccine. We are currently part of a very large phase III trial aimed at licensing this vaccine for widespread use next year."

Professor Adrian Hill, the University of Oxford's Director of the Jenner

Institute and Lakshmi Mittal and Family Professor of Vaccinology, and co-author of the paper, said, "We are delighted to find that a standard four dose immunization regime can now, for the first time, reach the high efficacy level over two years that has been an aspirational target for malaria vaccines for so many years."

The R21/Matrix-M malaria vaccine candidate created by the University of Oxford includes Novavax' proprietary saponin-based Matrix-M adjuvant and is licensed to Serum Institute of India.

The trial has been extended for another two years to assess if further booster doses will be necessary to maintain high efficacy over time.

Results from the key ongoing Phase III licensure trial to assess large-scale safety and efficacy in 4,800 children aged five to 36 months across four African countries, are also expected later this year.

Gareth Jenkins, Director of Advocacy at Malaria No More UK said, "Today's R21 vaccine results from Oxford's renowned Jenner Institute are another encouraging signal that, with the right support, the world could end child deaths from [malaria](#) in our lifetimes.

"But for new British inventions to achieve their potential, British leadership must continue, not least at the imminent US-hosted Global Fund to Fight AIDS, Tuberculosis and Malaria replenishment conference this September.

"This will be the new PM's first foreign policy test—for the sake of millions of children's lives, global health security, and British relations with its closest ally, it's a test they cannot fail."
