

Studies show children don't believe everything they are told

Children learn on their own through observation and experimentation. They also learn from what other people tell them, especially adults and authority figures like their parents and teachers. When children learn something surprising, they seek out additional information by asking questions or by testing claims. Prior research shows that *whether* children explore adults' surprising claims varies by age, with children over six years of age more likely to seek out additional information than four- and five-year-olds. However, there is limited research about *why* children seek information in response to being told something surprising from adults. A new study published in *Child Development* by researchers at the University of Toronto and Harvard University aims to answer this question.

"The research shows that as [children](#) age, they become more skeptical of what adults tell them," said Samantha Cottrell, senior lab member from the Childhood Learning and Development (ChiLD) Lab at the University of Toronto. "This explains why [older children](#) are more likely to try to verify claims and are more intentional about their exploration of

objects."

Across two preregistered studies, researchers set out to clarify whether and why children explore surprising claims.

In the first study, which was conducted in-person between September 2019 and March 2020, 109 children ages four- to six-years-old were recruited from the Greater Toronto Area, Canada. Due to the COVID-19 pandemic, the laboratory was shut down for in-person testing in March 2020, which resulted in lower testing numbers than originally planned. Parents of 108 of the 109 children reported on the ethnicity of their child: 49% described their child as White, 21% Mixed Ethnicity or Race and 19% Southeast Asian. Nearly all parents answered questions about their educational background with 18% of children having parents who did not attend university, 34% having one parent who attended university and 48% having two parents who attended university.

Children were presented with three familiar objects: a [rock](#), a piece of sponge-like material and a hacky sack. An experimenter began by asking children, "Do you think this rock is hard or soft?" All children stated that the rock was hard. Children were then randomly assigned to be told something that contradicted their beliefs about the world ("Actually, this rock is soft, not hard") or told something that confirmed their intuition ("That's right, this rock is hard"). Following these statements, all children were again asked, "So, do you think this rock is hard or soft?" Almost all children who heard claims that aligned with their beliefs continued to make the same judgement as before: that the rock was hard. In contrast, few of the children who were told that the rock was soft continued to make the same judgement as before. The experimenter then told children that they had to leave the room for a [phone call](#) and left children to explore the object on their own. Children's behaviour was video-recorded. The study found that most children regardless of age

engaged in testing surprising claims. The authors hypothesized that previously reported age differences in children's exploration of surprising claims might reflect developments in children's ability to use exploration to test more complex claims. It could also be that with increasing age, the motivation behind children's exploration changes, with [younger children](#) exploring because they believed what they had been told and wanted to see the surprising event and older children exploring because they were *skeptical* of what they had been told.

In the second study, which was conducted between September and December 2020, 154 4- to 7-year-old children were recruited from the same area as in the first study. Parents of 132 of the 154 children reported their ethnicity as 50% White, 20% Mixed Ethnicity or Race and 17% Southeast Asian. Nearly all parents answered questions about their [educational background](#) with 20% of children having parents who did not attend university, 35% having one parent who attended university and 45% having two [parents](#) who attended university.

Over Zoom (due to COVID-19 restrictions), an experimenter shared their screen and presented each participating child with eight vignettes. For each vignette, children were told that the adult made a surprising claim (for example, "The rock is soft" or "The sponge is harder than the rock") and were asked what another child should do in response to that claim and why they should do that. The results indicate that older children (six- and seven-year-olds) were more likely than younger children to suggest an exploration strategy tailored to the claim they heard (that is, touching the rock in the first example but touching the rock *and* the sponge in the second example). The results also show that with increasing age, children are increasingly justifying exploration as a means of verifying the adult's surprising claim. These findings suggest that as children age, even when they are equally likely to engage in exploration of surprising claims, they become more aware of their doubts about what adults tell them, and as a result, their [exploration](#) becomes more intentional, targeted and efficient.

"There is still a lot we don't know," said Samuel

Ronfard, assistant professor at the University of Toronto and lab director at the Childhood Learning and Development (ChiLD) Lab. "But, what's clear is that children don't believe everything they are told. They think about what they've been told and if they're skeptical, they seek out additional information that could confirm or disconfirm it."
