

Novel bioink capable of constructing physiological blood vessels

October 26 2022

Bioengineered blood vessels demonstrated physiological characteristics of real blood vessels, including strong vasoconstriction, vasodilation, perfusability and more. Credit: Shrike Zhang lab/BWH

Researchers at the Brigham used bioengineering advancements to improve 3D bioprinting of vascular tissues with functional and mechanical hallmarks. The researchers also showed the possibility of using these vessels for SARS-CoV-2 pseudoviral testing.

Cardiovascular diseases (CVDs) remain among the leading causes of global morbidity and mortality. In patients with CVD, [blood vessels](#)—which transport blood, oxygen, and nutrients—can become constricted

or obstructed, leading to numerous complications.

While revascularization and grafting are common procedures carried out during surgeries, biofabricated grafts used during these operations can have many drawbacks, for example, weak mechanical strength. To overcome these issues, researchers at the Brigham used bioengineering advancements to improve 3D bioprinting of vascular tissues with functional and mechanical hallmarks.

The team used crosslinking properties of natural polymers to develop a double-network hydrogel bioink capable for bioprinting [conduits](#). These conduits had key physiological characteristics of blood [vessels](#) including strong vasoconstriction, vasodilation, perfusability, and barrier performance comparable to native vessels. In line with the ongoing COVID-19 pandemic, the researchers also showed the possibility of using these vessels for SARS-CoV-2 pseudoviral testing.

"The vessels we have printed truly mimic a lot of the mechanics of native vessels," said senior corresponding author, Y. Shrike Zhang, Ph.D., of the Division of Engineering in Medicine. "This research demonstrates the potential for such conduits to serve as vascular models for grafts in vascular surgeries, other disease studies, and broad biomedical applications." The other co-corresponding authors included Xuanhe Zhao, Ph.D., of the Department of Mechanical Engineering at MIT, and C. Keith Ozaki, MD, of the Division of Vascular and Endovascular Surgery at the Brigham.

The study is published in *Science Advances*.
